

“Figure 7 illustrates the relationship between predicted and observed TCDD levels based on the assumed TCDD emission profile between 1962-1975.

The y-intercept of 10.34 pg/g lipid indicates the tendency of the model to overpredict observed TCDD values. This may be partly explained by the

assumed deposition rate used in the model overestimating ambient air TCDD concentrations and hence inhalation and exposed produce intakes

during the emission period which are predicted to be a significant exposure pathways.”

The y-intercept for the 24 retargeted selections after 1973 was 19.568 pg/g lipid indicating overprediction of the 1973-87 exposures this was

reduced to a y-intercept of 10.34 pg/g lipid when the 28 arrivals from 1960-1971 periods y-intercept of 0.7302 pg/g lipid was merged in Fig 7.
